## Section 2.6

Implicit Differentiation

## PROCEDURE FOR IMPLICIT DIFFERENTIATION

1. Assuming $y$ is a function of $x$, differentiate both sides with respect to $x$ using the chain rule for $y$ terms.
2. Collect the terms with $\frac{d y}{d x}$ on one side and the other terms on the other side.
3. Factor out $\frac{d y}{d x}$.
4. Divide both sides by the factor to leave $\frac{d y}{d x}$ by itself.

If the formula is NOT written this way, we say that $y$ is an implicit function of $x$.

## EXPLICIT AND IMPLICIT FUNCTIONS

Definition: The function $y$ is a explicit function of $x$ if the formula is written in the form

$$
y=\text { expression with } x \text { 's. }
$$

## EXAMPLE

Below is the same function defined explicitly and implicitly.

EXPLICIT: $y=x^{2 / 3}$
IMPLICIT: $y^{3}=x^{2}$

| EXAMPLE |
| :--- |
| Below is the same function defined explicitly |
| and implicitly. |
| EXPLICIT: $y=x^{2 / 3}$ |
| IMPLICIT: $y^{3}=x^{2}$ |
|  |

## IMPLICIT DIFFERENTIATION

Many times if a function is defined implicitly, it is difficult (or impossible) to write it explicitly. To take the derivative of an implicitly defined function, we use implicit differentiation.
